Technical Paper

Bitcoin: A Peer-to-Peer Electronic Cash System

Satoshi Nakamoto

October 31, 2008

Abstract

A purely peer-to-peer version of electronic cash would allow online payments to be sent directly from one party to another without going through a financial institution. Digital signatures provide part of the solution, but the main benefits are lost if a trusted third party is still required to prevent double-spending. We propose a solution to the double-spending problem using a peer-to-peer network. The network timestamps transactions by hashing them into an ongoing chain of hash-based proof-of-work, forming a record that cannot be changed without redoing the proof-of-work. The longest chain not only serves as proof of the sequence of events witnessed, but proof that it came from the largest pool of CPU power. As long as a majority of CPU power is controlled by nodes that are not cooperating to attack the network, they'll generate the longest chain and outpace attackers. The network itself requires minimal structure. Messages are broadcast on a best effort basis, and nodes can leave and rejoin the network at will, accepting the longest proof-of-work chain as proof of what happened while they were gone.

1. Introduction

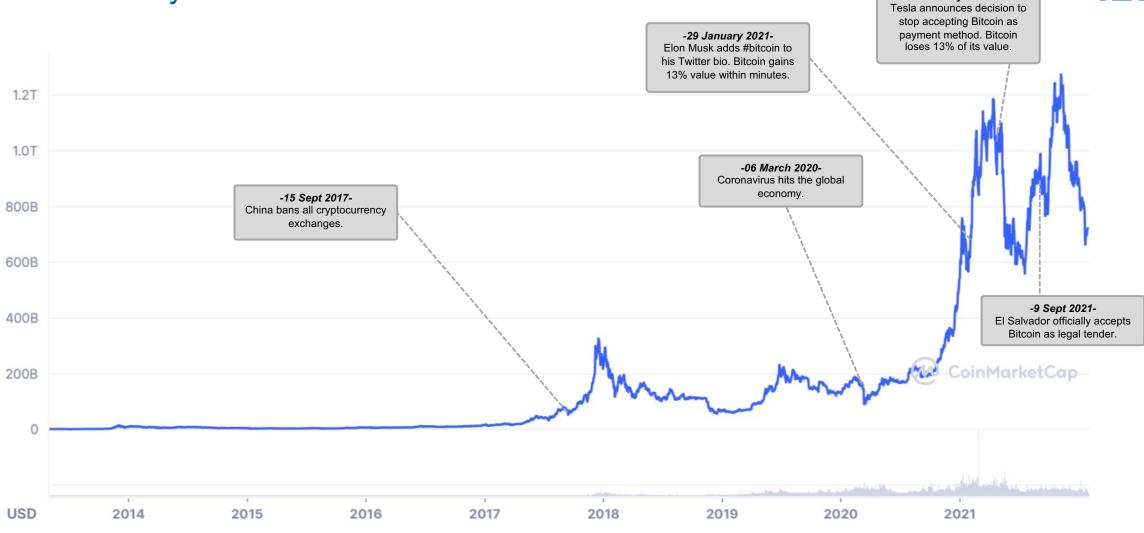

Commerce on the Internet has come to rely almost exclusively on financial institutions serving as trusted third parties to process electronic payments. While the system works well enough for most transactions, it still suffers from the inherent weaknesses of the trust based model. Completely non-reversible transactions are not really possible, since financial institutions cannot avoid mediating disputes. The cost of mediation increases transaction costs, limiting the minimum practical transaction size and cutting off the possibility for small casual transactions,

- This is a technical paper published online in the year of the financial crisis.
- Satoshi Nakamoto wrote a paper in 2008 about "Bitcoin: A Peer-to-Peer Electronic Cash System"
- The real identity of Satoshi Nakamoto remains unknown. We don't know whether it was a single person or a group.
- In January 2009 the first block of the Bitcoin blockchain was mined.
- In contrast to public opinion, Bitcoin was not invented because of the financial crisis. Satoshi Nakamoto said he started working on Bitcoin in May 2007 (in contrast the financial crisis started in August 2007).

-12 May 2021-

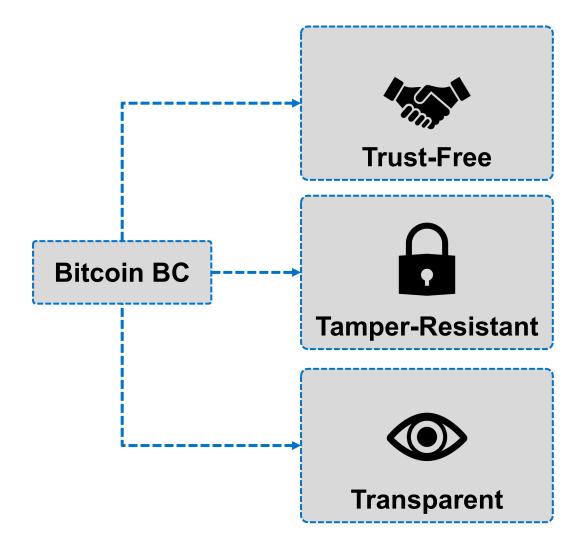

¹A decentralized organization created to allow people to lend and borrow cryptocurrencies.

Key Properties of the Bitcoin Blockchain

It has three key properties:

- **Trust-Free**: The system does not require a third party which controls or maintains the system.
- Tamper-Resistant: The system is resistant to manipulation. The history of events cannot be changed.
- **Transparent**: Every participant of the system can read and validate all information and the current state.

Bitcoin Blockchain

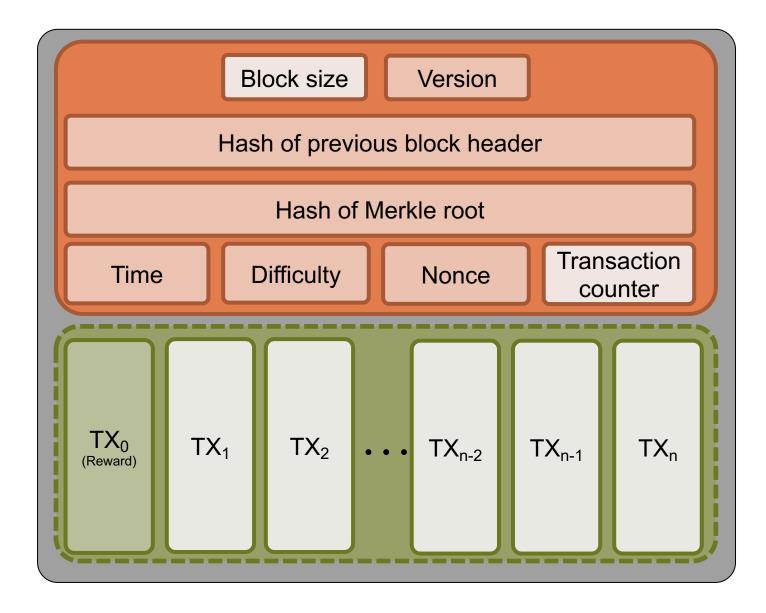

Block Details

- The hash of the previous block creates the chaining.
- The hash of the Merkle root node of a Merkle tree structure with all transactions (as explained in Chapter 2).
- The nonce is required for the consensus mechanism in the network.
- The block's hash used for chaining is calculated from the *version* until the nonce field.
- The height of the block is stored in the coinbase transaction. (TX₀)

Genesis Block

Blocks have to reference their predecessor → How does a blockchain start?

Bitcoin's genesis block¹:

- mined at 2009-01-03 18:15:05
- references a previous block with hash 0
- contains only the mining reward transaction → first 50 BTC which can never be spent

The fact that it cannot be spent is based on the source code of the current bitcoin-core client². The client searches through all blocks in ConnectBlock and processes all transactions but skips the genesis block.

Data Contained in the Genesis Block

- 6. Storing Bitcoins

Account-based Ledger

Create 25 coins and credit to Alice signed by miners		
Transfer 17 coins from Alice to Bob signed by Alice		
Transfer 8 coins from Bob to Carol signed by Bob		
Transfer 5 coins from Carol to Alice signed by Carol		
Transfer 15 coins from Alice to Bob signed by Alice		

Alice	Bob	Carol
25	0	0
8	17	0
8	9	8
13	9	3
-2	24	3

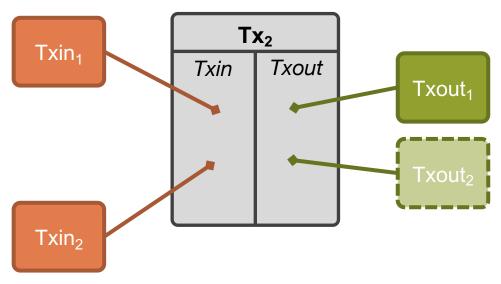

World State

- Transactions
- Intuitively: We consider Bitcoin to use an account-based ledger. However, an account-based approach takes a lot of effort to track the balances of every account.
- In reality, Bitcoin keeps track of the transactions an account has received and does not add up account balances (on the chain).
- Transactions lead to a "world-state" of accounts and allow to calculate account balances off-chain (e.g., in a wallet).
- By using a transaction-based ledger, Bitcoin enables wallet owners to define conditional transactions using Bitcoin Script¹.

¹Bitcoin Script is a stack-based scripting language used in Bitcoin transactions. It will be covered further in the upcoming exercises.

Transaction-based Ledger

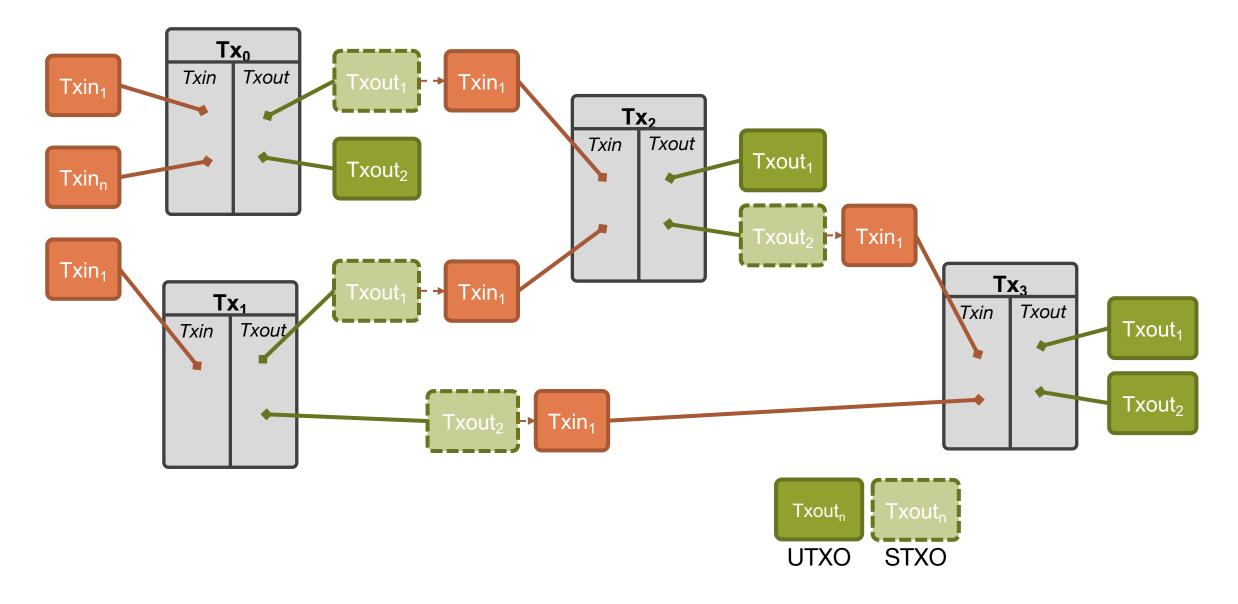

- Transactions (Tx) have a number of inputs and a number of outputs.
 - Inputs (Txin): Former outputs, that are being consumed
 - Outputs (Txout): Creation of new coins and transfer of coin ownership
- In transactions where new coins are created, no Txin is used (no coins are consumed)
- Each transaction has a unique identifier (TxID). Each output has a unique identifier within a transaction. We refer to them (in this example) as #TX[#txout], e.g., 1[1], which is the second Txout of the second transaction.

Transactions Connected by Inputs and Outputs

Transaction-based Ledger

0 Txin: Ø

Txout: 25.0 → Alice

1 Txin: 0[0]

Txout: $17.0 \rightarrow Bob$, $8.0 \rightarrow Alice_{signed by Alice}$

2 Txin: 1[0]

Txout: 8.0 → Carol, 9.0 → Bob signed by Bob

3 Txin: 1[1]

Txout: 6.0 → David, 2.0 → Alice signed by Alice

Example:

- 0. No input required, as coins are created.
- 1. The Tx is used as an Txin. Two Txout are created, one to Bob and one to Alice. (1[0] and 1[1]) The Tx is signed by Alice.
- 2. Uses first Txout of Tx1. Creates two Txout to Carol and Bob, signed by Bob.
- 3. Uses second Txout of Tx1. Creates two Txout to David and Alice, signed by Alice.

Further remarks

Change Address:

Why does Alice have to send money back to herself? In Bitcoin, either all or none of the coins have to be consumed by another transaction. The address the money is sent back to is called a *change address*. This enables an efficient verification, as one only has to keep a list of **unspent transaction outputs** (**UTXO**).

Consolidating funds:

Instead of having many unspent transaction outputs, a user can create a transaction that uses all UTXO she has and creates a single UTXO with all the coins in it.

Joint payments:

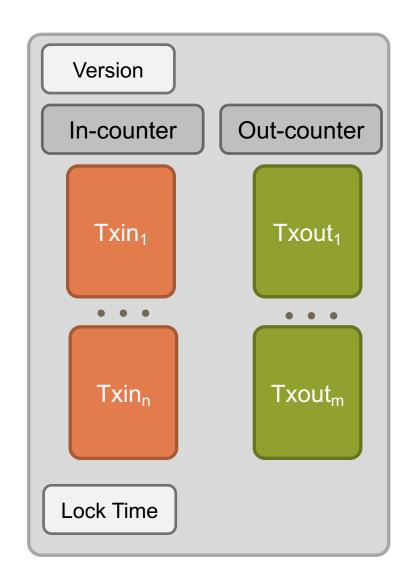

Two or more parties can combine their inputs and create one output. Of course, it requires signatures from all involved parties.

An Advanced Look at Transactions

As previously stated, transactions consist of inputs and outputs following these principles:

- All inputs reference an existing unspent output or a coinbase transaction.
- Inputs and outputs contain scripts
 (scriptSig, scriptPubKey) for verification.
- Output scripts (scriptPubKey) specify the conditions to redeem their value.
- Input scripts (scriptSig) provide a signature to redeem the referenced output.
- Only outputs store the BTC value and the receiver's address.
- All coins have a history (inputs/outputs) up to the original coinbase transaction that created them.

Input format

Txin

- previous transaction hash
- previous Txout-index
- script length
- scriptSig

Output format

Txout

- value in *Satoshi* (=10⁻⁸ BTC)
- script length
- scriptPubKey

Logical Data Structure of Transactions

```
"hash":"5a42590fbe0a90ee8e8747244d6c84f0db1a3a24e8f1b95b10c9e050990b8b6b",
"ver":1.
"vin sz":2,
vout sz":1.
"lock time":0,

  "value":"10.12287097",
  "scriptPubKey":"OP_DUP OP_HASH160 69e02e18b5705a05dd6b28ed517716c894b3d42e OP_EQUALVERIFY OP_CHECKSIG"
```

-Metadata

It contains the **size of the transaction**, the **number** of **inputs** and **outputs**, the version and a lock-time. The hash is also contained, which can be referenced.

-Inputs

An **array** of **all inputs**. Each input contains the previous transaction and the index of Txout. Also, a signature *script* is provided.

-Outputs

An **array** of **all outputs**. One output has two fields: the amount of the transferred coins¹ and the *scriptPubKey*.

An example transaction with two Txin and one Txout.

¹Note, that the sum of all output amounts has to be the same or smaller than the sum of all inputs. The difference is the transaction fee, which is covered in the chapter "Bitcoin Consensus".

Validation of Transactions

Whenever a transaction is validated, it must pass a long list of checks. Simplified, they look like this:

- Check syntactic correctness
- Make sure neither in or out lists are empty
- Check that size in bytes <= MAX_BLOCK_SIZE
- Each output value, as well as the total, must be in legal money range
- No input may be a coinbase transaction input
- Check that each input ...
 - a) references an old output
 - b) references an old output not yet referenced in another transaction (in block or in memory pool)
 - contains the correct authorization to spend that old output
 - d) ... satisfies the conditions defined by the script
- Check that the sum of output values <= sum of input values
- Add to transaction pool
- Relay transaction to peers

Gossip Protocol

- Bitcoin itself consists of different users and nodes. We distinguish between wallet owners, light nodes, full nodes and miners. (More on that topic later)
- They communicate in a decentralized fashion, meaning that no single entity or node is superior.
- To communicate, they need to have clear rules
 - How to find other nodes (bootstrapping)
 - How the sync the blockchain
 - How to send and receive transactions
 - How to send and receive blocks
- The basic network uses a peer-to-peer gossip protocol. Messages about new blocks or transactions are validated and then broadcasted. To prevent a second broadcast, the node keeps track of the transactions and blocks sent by itself.

An advanced look into the verification of messages containing transactions or blocks provides The Bitcoin Wiki: Protocol Rules

Bootstrapping of Nodes

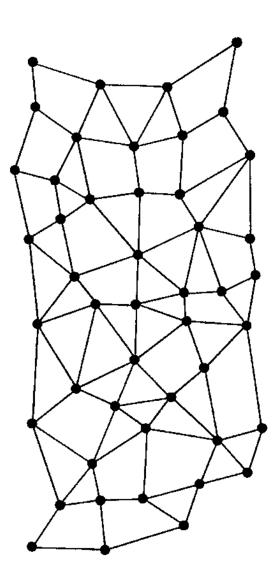

ТШ

Client Node Discovery

How are new nodes introduced into the Bitcoin network?

There are several ways:

- (deprecated) Get to know new clients via IRC-channels
- Hard-coded DNS-services which offer IP-addresses of nodes
- Hard-coded seed addresses (last resort)
- Addresses stored in a database maintained locally (to be loaded after a restart)
- Command-line provided addresses
- Text-file provided addresses

Roles in the Bitcoin Network

Full nodes are almost always a miner.

Wallet Owner (User)

- The wallet owner owns different private keys to unspent transaction outputs (UTXOs).
- He is the owner of all stored currencies on these addresses.
- He sends money by signing and publishing new transactions to a connected light node, full node or miner.

Full Node (Software)

- The full node maintains the complete blockchain. Its record of the chain is complete, it contains every single transaction and block until the genesis block.
- Is connected to other full nodes and exchanges information. Namely:
 - Validates every transaction and block it receives
 - Relays all new transactions and blocks

Miner (Software)

- The miner needs the same record as a full node in order to work properly. He also is connected to other nodes and maintains the network.
- Additionally, the miner is responsible for creating new blocks by trying to solve the mining puzzle.
- The miner gets rewarded by creating new blocks.

Light Node (Software)

- The light node can act as a relay for transactions of one wallet owner.
- It validates whether a single transaction of the wallet owner was executed correctly.
- The light node also requires a full node to connect to the network.
- Almost no relevance in practice today. Today, centralized services are used to create transactions.

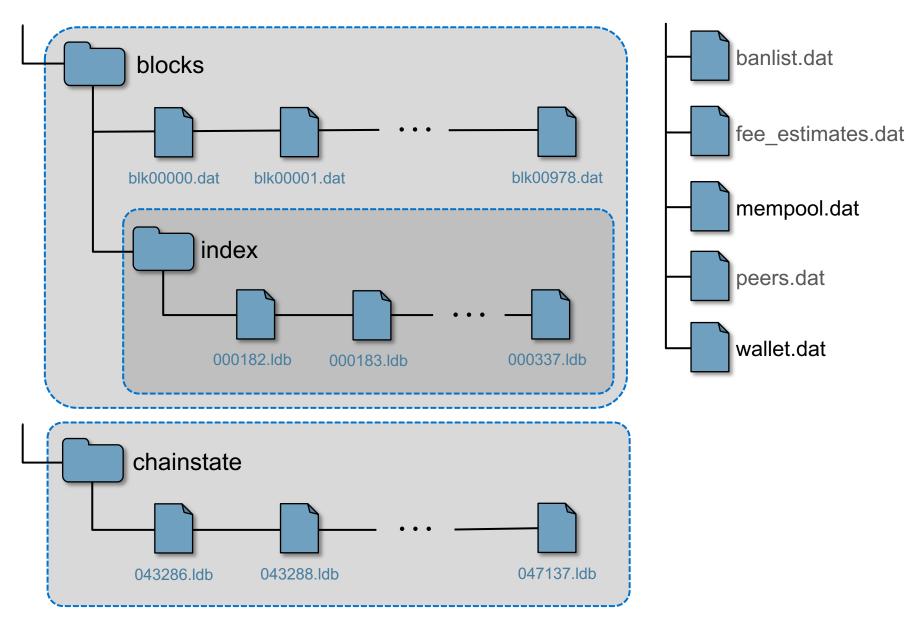

Anatomy of the Bitcoin Blockchain

Raw data is on a disk.

Miners and full nodes organize their data in a certain way. (Bitcoin core)

As of February 2022, the total data size of the Bitcoin blockchain is 388 GB.

Anatomy of the Bitcoin Blockchain

blocks and blocks/index

Contains .blk files that contain the actual blockchain in raw network format; **index** contains a database which stores the location of each block on the disk keyed with its hash.

chainstate

A LevelDB (leveldb.org) database with all currently unspent transaction outputs in the system (UTXO). This is used when operating a Bitcoin node in favor of the raw blockchain data.

mempool.dat

A list of unconfirmed transactions to be part of a future block.

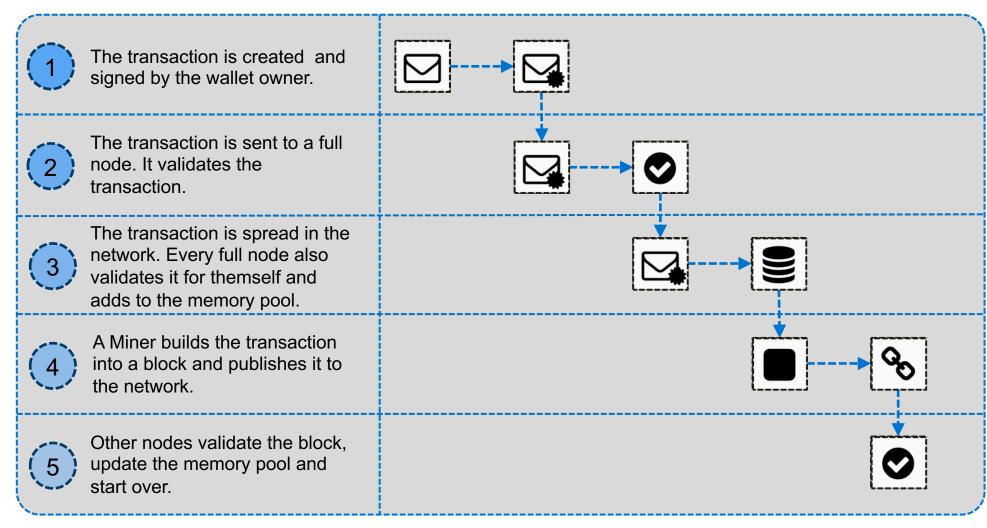

wallet.dat

Data regarding the user's (owner of the node) personal wallet.

A Newly Created Transactions Way into a Block

A high-level representation of how transactions are included in blocks.

MultiSig Address

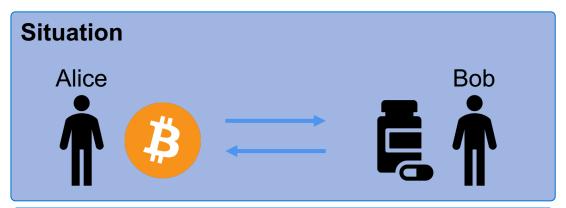

- A N/M multisig address is an address which has following properties
 - It requires more than one signature
 - N defines the number of required signatures
 - M defines the number of maximum signatures
- A 2/3 multisig address requires two arbitrary signatures from a pool of three predefined signatures.

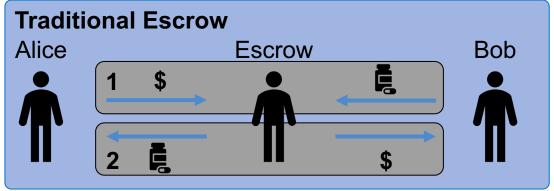

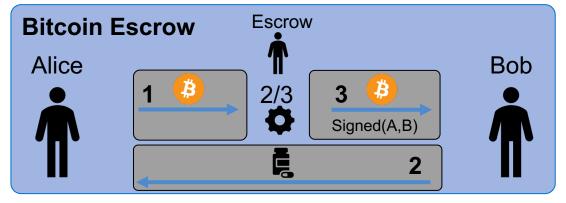

Escrow

ТΙΠ

- Alice and Bob want to do business together. Alice wants to buy some real-world product from Bob with Bitcoin. However, Alice does not want to send the Bitcoin before having the physical good, but Bob does not want to send the physical good before having the Bitcoin in his wallet.
- What to do? In traditional systems, an escrow would enable the transaction. The escrow would receive both the good and the money and exchange them.
- With Bitcoin (or other cryptocurrencies), this process can be enhanced. Alice creates a 2/3 multisig-address and transfers the money to it. Bob can now safely send his good.
- When the good arrives, both Alice and Bob can sign the transaction and Bob receives his money.
 - → If the exchange is correctly executed, the escrow is not involved.

Micropayments

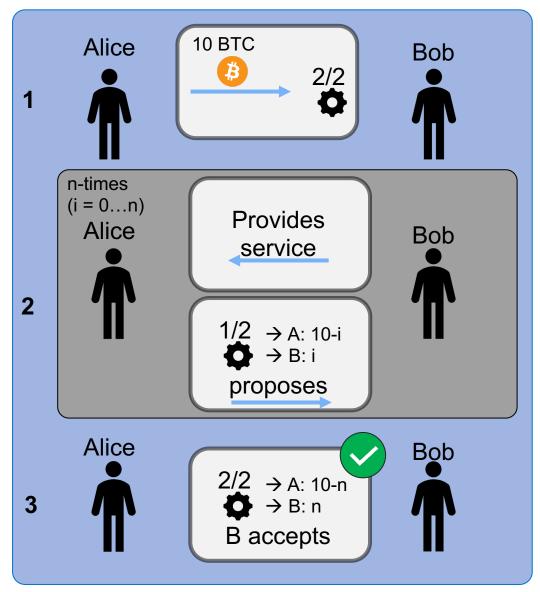

Alice wants to continuously use a service from Bob and pay a certain small amount of Bitcoin for each usage.

Creating new transactions every time won't work as:

- Too many transactions get created
- The fees for the transactions would be too high

An approach would be following:

- At the beginning, Alice send her maximum spendable amount to a 2/2 multisig address.
- Every time she consumes the service by Bob she signs a transaction locally for the multisig address, sending the accumulated amount to Bob and the change to herself. A message containing this incomplete transaction¹ is sent to Bob.
- If she is finished using the service, Bob will sign the last transaction he received and publish it on the network.
- → What is the problem?

¹ The transaction at this moment is rejected by the network, because the second signature is missing.

Lock Time

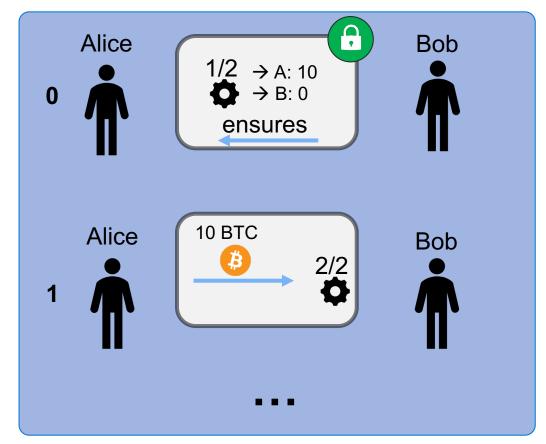

The problem is that Bob could decide **not to sign** the last transaction (or any transaction at all), leaving Alice's money stuck inside the multisig address.

However, there is a way around it:

In order to ensure that Alice receives her money back, she can demand from Bob to create a transaction from the multisig-address, transferring the complete funds back to Alice before creating it. This transaction contains the lock time¹ as the transaction should only be spendable after a certain amount of time *t* and if the output is not spent otherwise.

With this, it is safe to create a multisig address without having to worry if one receives the money back.

¹As there is no notion of time in Bitcoin, the lock time is given as the block height. Until this block height is reached, the transaction is invalid.

- P2P Network
- Types of Nodes
- 5. Bitcoin Use Cases
- 6. Storing Bitcoins

Storing Bitcoins

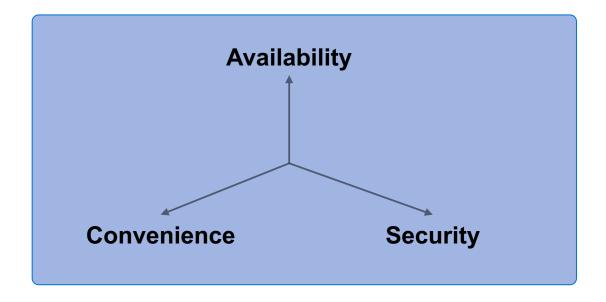

Storing Bitcoins is all about storing and managing secret keys.¹

Different approaches for storing and managing secret keys lead to different trade-offs between **availability**, **security** and **convenience**.

Availability: being able to access the keys when one wants to

Security: restricting access to the keys

Convenience: easy use

Of course: The simplest approach is to store the secret key on one's hard drive. What could *possibly* happen?

Cryptocurrency Wallets

Cold Storage

- Takes some time to "activate"
- Enhances security at the cost of convenience and availability
- Advantage: Cold Storage does not have to be online to receive coins

Hot Storage

- Is immediately available
- Enables convenience at the cost of availability and security
- Example: Storage on your pc / mobile

Wallet Types

Brain Wallet

- A brain wallet stores Bitcoins with nothing but a secret passphrase.
- There is no need for hard drives, paper or else to store information.
- Idea: a deterministic function to generate a private key out of a passphrase.
- However:
 - Source of randomness determines the security → offline guessing / password cracking
 - If passphrase is forgotten, bitcoins are lost forever
- Example: "witch collapse practice feed shame open despair creek road again ice least"

Paper Wallet

- Key material is printed to paper. Paper can be placed in secure places like safes or vaults.
- However, keep in mind:
 - Source of randomness
 - Side-Channel attacks
 - Infected computer / malware
 - Malicious paper-wallet generator
 - Monitored printer
 - Durability of paper
 - Durability of ink
 - Secure place: dark, 16-19°C, low humidity

Bitcoin Paper Wallet

Wallet Types (cont.)

Hardware Wallet

- Key material is stored on the hardware device.
- Additional: Generation of a 24-word passphrase. If device gets destroyed, the passphrase allows for a recovery.
- Device is designed to keep your private key private. Key is securely stored within the device.
- The display shows the amount and target of a transaction. The keys on the device allow for a confirmation or rejection of the transactions.
- Requires trust in manufacturer and intermediaries.
 (Never buy used hardware wallets!)

Hardware Wallet - Ledger Nano S

Online Wallet

- Let other people/ companies store your Bitcoins/ cryptocurrencies for you (custodial wallet).
- No access to the private key, coins can only used through a certain interface / website.
- Very common within most exchanges. The money is sent to the exchange, the account on the platform has now a new balance which can be traded or paid out.
- However: Very dangerous! Many exchanges got hacked, users lost their funds. Be careful!
